Indian Institute of Technology, Madras

Module – 2
Advanced Structural Analyses
Lecture – 29
Shear Centre IV

Friends we will continue with the discussion on topic Shear Centre, this is lecture 29 in module 2 where we are discussing some topics on Advance Structural Analyses under the NPTEL course title offshore structures and the special loads including fire resistance design.

(Refer Slide Time: 00:39)

Let us continue with the example what we discuss in the last lecture. So, thin walled section of uniform thickness t and this dimension was indicated as b_1 , and this dimension is indicated as beam and this becomes my axis of symmetry, we already know that when a section has at least one axis of symmetry, the shear centre will lie on this, let say this is my shear centre c where the vertical force will be applied to avoid twisting movement in the given cross section.

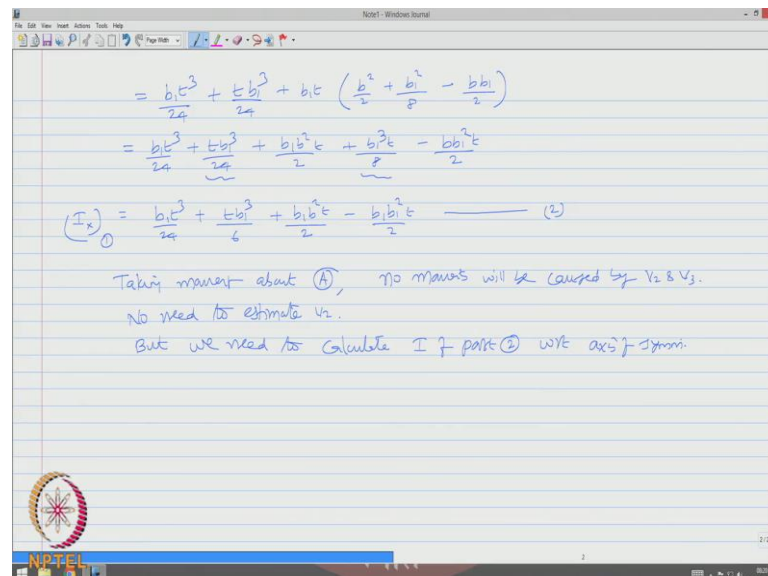

From this point we take the offset of the shear centre as e and let us call this point as point A ; if you look at the shear flow within the cross section, we know that this is V_1 , V_2 , V_3

and V_4 . To find V_1 we took a section, which is z from here from here and you derive that V_1 is $V t b^2$ by $\sqrt{2} I$, b by 2 minus b by 3 equation number 1; let us try to find the I value which is moment of inertia of the entire cross section about the axis symmetry. So, let us take this object separately and we know the dimensions of this yes b and thickness is t , it is got 2 axes, let us say this is my u axis and this is my v axis and let say this x dash x dash axis.

So, I can easily say that I_u is $b^3 t$ cube by 12 , and I_v is $t b^3$ cube by 12 , and we know that this angle is 45 degrees therefore, I_x dash can be calculated as $I_u \sin^2 45$ plus $I_v \cos^2 45$, which will be $b^3 t$ cube by $12 \sin^2 45$ is 1 by 2 , plus $I_v t b^3$ cube by 12 and 1 by 2 which tells me is $b^3 t$ cube by 24 , plus $t b^3$ cube by 24 dash, but I want to find about this axis the moment of inertia. So, I_x using parallel axis theorem will be I_x dash plus $A k^2$, which I say $b^3 t$ cube by 24 , plus $t b^3$ cube by 24 , plus b into t is the area and k is actually the centroidal distance of this from here that is may k .

Which will be $b \sin 45$, minus b by $2 \sin 45$ that is the distance for whole square, which can be $b^3 t$ cube by 24 , plus $t b^3$ cube by 24 , plus $b t b$ by $\sqrt{2}$, minus b by $2 \sqrt{2}$ the whole square.

(Refer Slide Time: 07:09)

Handwritten mathematical derivation for the moment of inertia I_x of a square rotated 45° . The derivation shows the expansion of the parallel axis theorem formula:

$$= \frac{b^3 t^3}{24} + \frac{t b^3}{24} + b t \left(\frac{b^2}{2} + \frac{b^2}{2} - \frac{b b t}{2} \right)$$

$$= \frac{b^3 t^3}{24} + \frac{t b^3}{24} + \frac{b^3 t}{2} + \frac{b^3 t}{2} - \frac{b b^2 t}{2}$$

$$(I_x)_0 = \frac{b^3 t^3}{24} + \frac{t b^3}{6} + \frac{b^3 t}{2} - \frac{b b^2 t}{2} \quad \text{--- (2)}$$

Taking moment about (A), no moments will be caused by V_2 & V_3 .
 No need to estimate V_2 .
 But we need to calculate I of part (2) w.r.t axis of symm.

Which can be $b^3 t$ cube by 24 , plus $t b^3$ cube by 24 , plus $b^3 t$, b square by 2 , plus b^3 square by 8 minus $b b$ by 2 . So, expanding further $b^3 t$ cube by 24 , plus $t b^3$ cube by 24 ,

plus $b^2 t$ by 2, plus b^3 by 8, minus $b^2 t$ by 2 which can be further simplify because I have a term b^3 here and b^3 here.

So, let us say $b^2 t$ by 24, plus b^3 by 6, plus $b^2 t$ by 2, minus $b^2 t$ by 2; let say this is I_x only of the component and let say first component equation 2. Now let us look back this figure, if you take moment about the point a since V_2 and V_3 pass through this point they will create no moment, only V_1 and V_4 you will create moment. The distance of V_1 from this point will be equal to b therefore, we can take moment about the point A, no moments will be caused by V_2 and V_3 therefore, no need to estimate V_2 .

But we need to calculate the moment of inertia of the part 2 with respect to axis of symmetry that is required.

(Refer Slide Time: 10:13)

part 2

$$I_{uu} = \frac{t b^3}{12}$$

$$I_{vv} = \frac{b t^3}{12}$$

$$I_{x'} = I_u \cos^2 45^\circ + I_v \sin^2 45^\circ$$

$$= \frac{t b^3}{12} \left(\frac{1}{2}\right) + \frac{b t^3}{12} \left(\frac{1}{2}\right)$$

$$= \frac{t b^3}{24} + \frac{b t^3}{24}$$

$$I_{xx} = I_{x'} + A k^2$$

$$= \left(\frac{t b^3}{24} + \frac{b t^3}{24}\right) + (b t) \left(\frac{b}{2} \sin 45^\circ\right)^2$$

$$= \left(\frac{t b^3}{24} + \frac{b t^3}{24}\right) + b t \left(\frac{b^2}{8}\right) = \frac{t b^3}{24} + \frac{b t^3}{24} + \frac{b^3 t}{8} = \frac{4 t b^3}{24} + \frac{b t^3}{24}$$

$$I_{xx} = \frac{t b}{24} (4 b^2 + t^2)$$

So, let us take part 2 which is like this, u u axis, in this is my v v axis say this is my x dash x dash axis, this is angle is 45 degrees. So, we know now that and the dimensions are this dimension is b and this thickness and this t therefore, I_{uu} of part 2, this is part 2, I_{uu} is $t b^3$ by 12 and I_{vv} is $b t^3$ by 12, $I_{x'x'}$ will be $I_u \cos^2 45$, plus $I_v \sin^2 45$ which will be $t b^3$ by 12, 1 by 2 plus $b t^3$ by 12, 1 by 2 which gives me $t b^3$ by 24, plus $b t^3$ by 24.

So, I want to find I_{xx} there is see this xx axis passes through this point, this may actually axis of symmetry which a call as xx axis in this case. So, I should say this is I_{xx} dash x dash plus a k square parallel axis theorem, which will be t cube b cube by 24, plus b t cube by 24 plus b into t is the area and k will be b by 2 $\sin 45$ the whole square, which gives me t cube b cube 24 plus b t into. So, which will give me; I have 2 b cube terms, let us add this it will be 4 t cube 24 plus t cube b by 24, which means t b by 24, 4 b square plus t square that is I_{xx} of part 2.

(Refer Slide Time: 14:01)

Handwritten mathematical derivation for the moment of inertia I_{xx} of a section. The derivation shows the calculation of I_{xx} for a part, then the calculation of I_{xx} for the whole section using the parallel axis theorem. It also shows the calculation of the centroidal distance 'e' by taking moments about a point A.

$$= \left(\frac{bt^3}{24} + \frac{bt^3}{24} \right) + bt \left(\frac{b}{8} \right)^2 = \frac{bt^3}{12} + \frac{bt^3}{8} = \frac{4bt^3}{24} + \frac{3bt^3}{24}$$

$$I_{xx} = \frac{bt^3}{24} (4b^2 + t^2)$$

I_{xx} for the whole section

$$= [I_{xx}b + I_{xx}t]^2$$

$$= \left[\left(\frac{bt^3}{24} + \frac{bt^3}{6} + \frac{bt^3}{2} - \frac{bb^2t}{2} \right) + \frac{bt}{24} (4b^2 + t^2) \right]^2$$

To find 'e', Take moments about A

$$V_e = V_1 b + V_4 b$$

$$V_e = (V_1 + V_4) b$$

$$V_e = 2V_1 b \quad \text{--- (3)}$$

V_1, V_4, b are known. e can be computed ✓

Now, I want to find I_{xx} of the whole section, which will be now equal to I_{xx} of part 1 plus I_{xx} of part 2 into 2 there are 2 such parts.

Which will be b t cube by 24, plus t b cube by 6, plus b t square by 2, minus bb t square by 2 that is path 1, plus t b by 24, 4 b square by t square, now the whole multiplied by 2. Now I can find e ; to find e take moments about A, the taking moment about this part; so I should say now b into b , V into e will be equal to V into b , plus V into b which is V into b plus V into b , which essentially is $2V$ into b . So, in this equation V , V into b and b are known e can be computed or on the other hand V into b is known in terms of V . So, they for still e can be computed. So, in this example we have seen how one can locate shear centre for sections which has at least one axis of symmetry.

(Refer Slide Time: 16:22)

(Unsymmetrical section) (u, v) are principal axes of inertia

Ex 1
 (1) To compute $(\bar{x}, \bar{y}) = C_g$

$$\bar{x} = \frac{\sum A \bar{x}}{\sum A}$$

$$= \frac{[(20 \times 2) \times 10] + [(40 \times 2) \times 20] + (36 \times 2) \times 1}{(20 \times 2) + (40 \times 2) + (36 \times 2)} = 10.8 \text{ mm}$$

$$\bar{y} = \frac{\sum A \bar{y}}{\sum A} = \frac{(20 \times 2) \times 1 + (40 \times 2) \times (39) + (36 \times 2) \times 20}{(20 \times 2) + (40 \times 2) + (36 \times 2)} = 23.9 \text{ mm}$$

(2) To find MoI (I_z & I_y)

Now, let us say to find shear sections or shear centre; to find or locate shear centre for sections which have no axes of symmetry, unsymmetrical sections; let us take an example is take this my unsymmetrical section, I am drawing let say is my z axis and this is my y axis and that becomes my Cg, which you need to locate and this section as no axis of symmetry, let us mark the dimensions of the section and say this is 40, this dimension over all is also 40 and this dimension is 20, the section as uniform thickness of 2 millimeters though on by. So, now, let us call this distance my z bar and this distance as y bar. So, the first step is to compute z bar y bar which are coordinates of the C g. So, we will use to find z bar sigma A z bar by sigma A, let us say 20 into 2 area of the first part, is the first part and Cg distance 10 plus 40 into 2.

So, this is the second part and the distance is 20, plus this remaining distance this value will be 40 minus 4 which is 36. So, this is the third part 36 into 2 into the distance of that from here is 1 divided by 20 into 2, plus 40 into 2, plus 36 into 2, which will give me z bar as 10.8 millimeters, this value is 10.8. Similarly y bar is sigma A y bar by sigma A, which is 20 into 2 into 1 that is the distance, 40 into 2 into 39 30 is the distance of the second piece plus 36 into 2 the distance of this Cg from here, we are both about this distance, which will be 36 by 2 is 18, 18 plus 2 is 20. So, 20 divided by 20 into 2 plus 40 into 2 plus 36 into 2.

(Refer Slide Time: 21:38)

(2) To find MoI (I_z & I_y)

$$I_z = \frac{20 \times 2^3}{12} + 20 \times 2 \times (22.9)^2 + \frac{40 \times 2^3}{12} + 40 \times 2 \times (15.1)^2 + \frac{2 \times 36^3}{12} + 36 \times 2 \times (3.9)^2 = 4.82 \times 10^4 \text{ mm}^4$$

$$I_y = \frac{2 \times 20^3}{12} + (20 \times 2) \times (0.8)^2 + \frac{2 \times 40^3}{12} + 40 \times 2 \times (20 - 10.8)^2 + \frac{36 \times 2^3}{12} + 36 \times 2 \times (9.8)^2 = 2.57 \times 10^4 \text{ mm}^4$$

$$I_{xy} = \int_A (xy) \, dA = (20 \times 2) \times (0.8) \times (22.9) + (40 \times 2) \times (-9.2) \times (-15.1) + (36 \times 2) \times (9.8) \times (3.9) = +1.46 \times 10^4 \text{ mm}^4 \quad (I_{xy} \text{ can also be } -ve)$$

I get \bar{y} as 23.9 millimeters. So, you have to look at the C_g , now the next step lies to find the moment of inertia which is I_z and I_y . So, from the first principles we can find I_z as $\frac{20 \times 2^3}{12}$, plus $20 \times 2 \times 22.9^2$, we look at this we are interested in finding let say this distance. So, $23.9 - 1$; so 22.9^2 that is what you're writing here, plus $\frac{d^3 b}{12}$ a k square. So, this distance will be 15.1, is actually $39 - 23.9$ that is what you get, 15.1^2 , plus $\frac{2 \times 36^3}{12}$ that is by the part 3, plus $36 \times 2 \times 3.9^2$ square because this C_g will be from here.

$\frac{18 + 2 \times 20 \times 23.9}{36}$ refer 3.9^2 , which amounts to $4.82 \times 10^4 \text{ mm}^4$; let us find I_y by $\frac{d^3 b}{12}$, plus a k square, let say I am talking about I_y , this is 20. So, this is 10 and 10.8. So, 0.8^2 , plus $\frac{2 \times 40^3}{12}$, $40 \times 2 \times 20$, minus 10.8^2 square plus $\frac{36 \times 2^3}{12}$ plus $36 \times 2 \times 9.8^2$. I get I_y as $2.57 \times 10^4 \text{ mm}^4$, I can also find I_{xy} . I_{xy} is summation $\int xy \, dA$ for the whole area. So, let us do it or part 1 20×2 is the area and the z value and the y value, plus part number 2, 40×2 and the z value is minus 9.2 and the y value is minus 15.1 plus the third part into 2 is 9.8 positive and 3.9 positive.

So, I get this value as plus 1.46×10^4 . Please note that I said by can also be negative, please understand this and this case it is positive.

(Refer Slide Time: 26:07)

Handwritten derivation on a Notepad window:

$$\tan(2\alpha_1) = -\frac{2I_{yz}}{I_z - I_y}$$

$$= -\frac{2 \times 1.46 \times 10^4}{(4.82 - 2.57) \times 10^4}$$

$$\tan(2\alpha_1) = -1.298$$

$$\alpha_1 = +63.81^\circ$$

$$I_u = \frac{I_y + I_z}{2} + \frac{I_z - I_y}{2} \cos 2\alpha - I_{yz} \sin 2\alpha$$

$$= \frac{(2.57 + 4.82) \times 10^4}{2} + \frac{(4.82 - 2.57) \times 10^4}{2} \cos(127.6^\circ) - 1.46 \times 10^4 \sin(127.6^\circ)$$

$$= 1.852 \times 10^4 \text{ mm}^4$$

$$I_v = I_y + I_z - I_u = (4.82 + 2.57 - 1.852) \times 10^4$$

$$= 5.538 \times 10^4 \text{ mm}^4$$

A circled note states: $I_{uv} = 0$

Once I know I_z , I_y and I_{yz} , we can find out the inclination of the principal axes of inertia by this equation, which we already derive $\tan 2\alpha_1$ is minus $2 I_{yz}$ by I_z minus I_y which in my case is minus $2 \times 1.46 \times 10^4$, by 4.82 minus 2.57 into 10^4 , we says $\tan 2\alpha_1$ is minus 1.298 , which tells me α_1 is 63.81 degrees, let us try to plot this. So, this is my u and my v and this angle is 63.81 degrees by just α_1 in my positive value.

So, these are u and v are principal axes of inertia, now I can find them I can determine them from the formal equation I_u is $I_y + I_z$ by 2 , plus z minus y by $2 \cos 2\alpha$ minus $yz \sin 2\alpha$, which can be 2.57 plus 4.82 into 10^4 by 2 , plus 4.82 minus 2.57 , into 10^4 by $2 \cos$ of 127.6 degrees, minus $1.46 \times 10^4 \sin$ of 127.6 degrees, which tells me this values 1.852 into 10^4 , mm to the power 4 , I can find I_v as I_y plus I_z minus I_u , which will be 4.82 plus 2.57 minus 1.852 of 10^4 , which tells me is 5.538 , 10^4 , mm to the power 4 .

So, I have I_u and I_v ; obviously, u and v principal axes of inertia, I_{uv} will be 0 .

(Refer Slide Time: 29:28)

Step 3 we need to apply load V \perp to uu axis

by taking moments of forces about pt(A), V_3 & V_2 will have no moments.

$$V_z = \int \tau da = \int \tau (t dz)$$

$$\tau = \frac{V A \bar{y}}{I_u t}$$

$$= \frac{V A \bar{v}}{I_u t}$$

$$= \frac{V}{I_u} \int \left(\frac{A \bar{v}}{t} \right) t dz$$

$$= \frac{V}{I_u} \int (z \bar{v}) dz \quad \text{It's important to find } \bar{v}$$

Now, after locating the principle axes of inertia our interest to find the shear centre, we need to apply load V that shear flows, perpendicular to u axis. So, let us say this is my object or this is my section, this is my z axis, this is my y axis, this is my u axis, v axis, this angle is more and these distances or also known this is 10.8 and this is 23.9 and this value is 40, this value is also 40, this value is 20 and this thickness is 2.

A shear flow is like this, let say this is my V_1 , this is my V_3 and this is my V_2 , V_3 and V_2 into sector this point. So, let us say I want to apply the force perpendicular u axis let say applied here applied here. So, I am interested in finding out actually this distance, interestingly if we call this point as point A, by taking movement about of forces about point A, V_3 and V_2 will have no component. So, let say only V into e will be there, let us cutter section at distance z and the C_g of the section is let say V_1 . So, V_1 is τda , which is integral $\tau t dz$, τ is $V A \bar{y}$ by $I_u t$, in my case it is going to be $V A \bar{v}$ by I_u into t . So, which will be going to equal to V by I_u , integral $A \bar{v}$ by t into $t dz$, which will be V by I_u integral $z \bar{v}$ into $V \bar{d} z$

Now, interestingly it is important to find \bar{v} of the C_g of the portion, this distance you want to find the $V \bar{d}$.

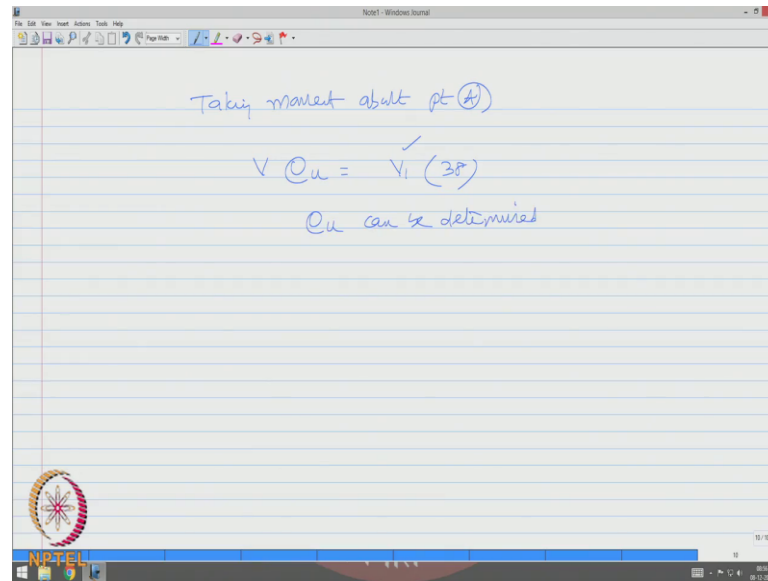

(Refer Slide Time: 34:31)

$$\begin{aligned}
 V &= -z \sin \alpha + y \cos \alpha \\
 &= -\left(-\left(20 - 10.8 - \frac{z}{2}\right) \sin(63.81^\circ)\right) \\
 &\quad + 22.9 \cos(63.81^\circ) \\
 &= -\left(-\left(9.2 - \frac{z}{2}\right) 0.9\right) + 10.11 \\
 &= 8.28 - 0.45z + 10.11 \\
 &= 18.39 - 0.45z \\
 V_1 &= \frac{Vt}{I_u} \int_0^{20} z(18.39 - 0.45z) dz \\
 &= \frac{Vt}{I_u} \left(\frac{18.39z^2}{2} - \frac{0.45z^3}{3} \right) \\
 V_1 &= \frac{V \times L}{1.852 \times 10^8} \left(\frac{18.39 \times 400}{2} - \frac{0.45(20^3)}{3} \right) \quad \text{--- (1)}
 \end{aligned}$$

We know V is actually equalled to $z \sin \alpha$ plus $y \cos \alpha$. So, if you look at any cross section? If I say this is my z , this is my y and this is my let say $d a$ and these are my u and v axis, and this is my α then I can easily say I resolve this negative side of v therefore, v is minus $z \sin \alpha$, plus $y \cos \alpha$. Now you will like to know the coordinates of this specific Cg in terms of v bar. So, which will be minus of minus 20 minus 10.8, minus z by 2 of $\sin 63.81$ degrees, plus $22.9 \cos 63.81$ degrees that is going to be my e value. Now the question is why this is negative? Can see here this is 20, the Cg of this point is on the negative side of z that is why it is minus.

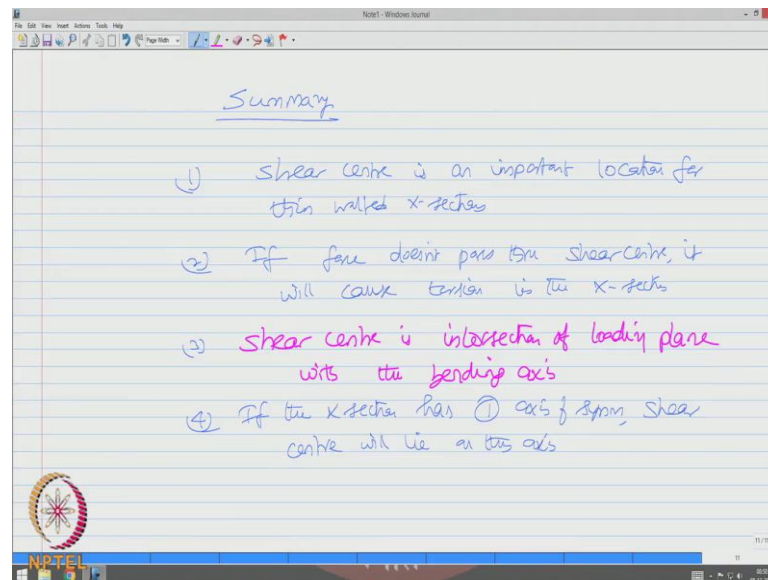

You are substituting minus, minus 9.2, minus z by 2.9, plus 10.1, which gives me 8.28 minus 0.45 z , plus 10.11 which will tell me 18.39 minus 0.45 z ; now, let us get back to be 1 which will be $V t$ by I_u , integral 0 to 20 z , into 18.39 minus 0.45 z of $d z$, which can be $v t$ by I_u , 18.39 z square by 2, minus 0.45 z cube by 3, which can be V into 2 by 1.852 into 10 power of 4 of 18.39 into 400 by 2, minus 0.45 20 cube by 3.

(Refer Slide Time: 38:31)

So, I can find V_1 by equation 1. Once I know V_1 , taking moment about A, I can say V into $e u$ is V_1 into 38, because 38 is the distance of C_g , in this point to this point that is this distance. So, V_1 is known in terms of V therefore, we will cancel and $e u$ can be determined.

(Refer Slide Time: 39:12)

So, friends the summary of all this 4 lectures, shear centre is an important location for thin walled cross sections. If force does not pass through shear centre, it will cause torsion in the cross section and shear centre is intersection of loading plane with the bending axis, if the

section has 1 axis of symmetry, shear centre will lie on this axis. We have seen examples to find out shear centre for cross sections having at least 1 axis of symmetry and also for cross section does not have even any one single axis of symmetry.

I hope you have understood these lectures and followed these examples, there are many more examples available in the literature please try to solve them and try to find out how you can estimate shear centre location for the given cross sections.

Thank you very much.
